AI Workshop - Lab 2-2: Intent Classification

In this lab, we'll build a system to classify customer text messages into different categories (called **intents**) using a powerful type of AI model called a transformer. Transformers are a key technology behind tools like ChatGPT and other modern language systems.

Data Overview

We're working with a dataset of customer text messages that has already been labeled with their intent (e.g., "Order Status", "Product Inquiry", "Account Help"). The goal is to teach the model to recognize these patterns so it can classify new messages correctly.

• Number of Categories: 27 different intents.

What You'll Learn

- **Transformers**: Get an introduction to these models and why they're so powerful for language tasks.
- Model Evaluation: Understand how to measure a model's performance and interpret its predictions.

```
In [1]: !pip install -Uq datasets transformers accelerate evaluate sentencepiece sac
```

For this lab, it's essential that we have a GPU available to speed up training. On Google Colab, you can enable a GPU by going to **Runtime > Change runtime type > Hardware accelerator > GPU.**

The following line of code will check if a GPU is available:

```
In [2]: import torch
  device = torch.device('cuda' if torch.cuda.is_available() else 'cpu')
  if device.type == 'cuda':
     print('GPU is available!')
  else:
     print('GPU is not available. Enable a GPU runtime in Colab under "Runtime")
```

GPU is available!

Loading the Dataset

Now that we've set up our environment and imported the necessary packages, let's begin by loading our dataset.

In this lab, we'll work with a dataset of **customer text messages** that have been labeled with their **intent**. Each sample in the dataset includes a text message and a corresponding label indicating the intent behind the message (e.g., inquiry, complaint, order request). This dataset will allow us to build and evaluate models for intent classification.

Steps:

1. Load the Dataset:

- Use the load_dataset function from the datasets library to download and load the dataset.
- The dataset we're using is hosted at "alexwaolson/customer-intents".

2. **Inspect the Dataset**:

• After loading, examine the training split (intents['train']) to understand its structure and the data it contains.

```
In [3]: from datasets import load_dataset
import pandas as pd

# Load the customer intents dataset
intents = load_dataset("alexwaolson/customer-intents")

# Display the training split
pd.DataFrame(intents['train'])
```

Out[3]:		message	label
	0	acn uhelp me to download my bill from Anna Fre	get invoice
	1	I need to notify of payment errors	payment issue
	2	I'm trying to open an standard account for my	create account
	3	checking invoices from Mr. Jones	check invoice
	4	I am waiting for a restitution of 1200 dollars	track refund
	•••		
	1550	mail me my invoice from Anna Freeman	get invoice
	1551	I have problems setting up another delivery ad	set up shipping address
	1552	is it possible to check what payment options y	check payment methods
	1553	have a question about a lost padsword	recover password
	1554	getting refund of money	get refund

1555 rows × 2 columns

The dataset consists of two key columns:

- **message**: Contains the text of the customer message.
- **label**: Contains the intent category for each message.

There are **27 possible intent categories** in this dataset. To understand the distribution of these categories, we can count the number of examples for each intent. This helps us determine whether the dataset is balanced (i.e., whether all categories have similar representation) or imbalanced (some categories have significantly more or fewer samples than others).

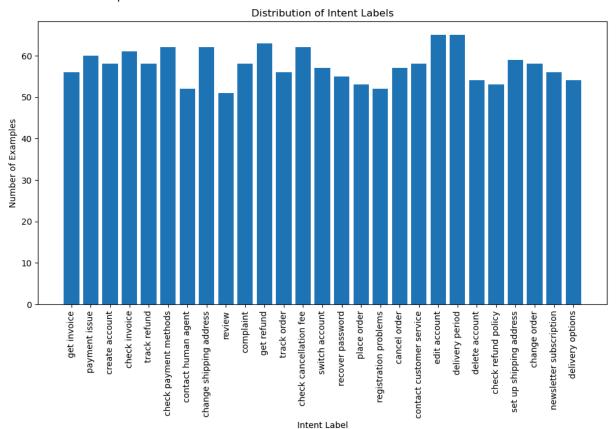

Run the code below to calculate the distribution of intent labels:

```
In [4]: from collections import Counter
import matplotlib.pyplot as plt

# Count the occurrences of each intent label in the training data
label_counts = Counter(intents['train']['label'])
print(f'Number of unique intents: {len(label_counts)}')

# Plot the distribution of intent labels
plt.figure(figsize=(12, 6))
plt.bar(label_counts.keys(), label_counts.values())
plt.xlabel('Intent Label')
plt.ylabel('Number of Examples')
plt.title('Distribution of Intent Labels')
plt.xticks(rotation=90)
plt.show()
```

Number of unique intents: 27

Zero-Shot Learning

One of the most powerful features of large language models is their ability to perform **zero-shot learning**. Unlike traditional models that require task-specific training, a zero-shot learning model can classify text based on its general understanding of language, even if it hasn't been explicitly trained on that specific task.

How It Works:

- Instead of fine-tuning the model, you provide it with a **prompt** that describes the task and possible labels (e.g., "What is the intent of this message?").
- The model uses its pre-trained knowledge to predict the most appropriate label.

This approach leverages the model's extensive training on a wide variety of text, making it flexible for many tasks.

Why Use Zero-Shot Learning?

- Quick Prototyping: No need to preprocess or fine-tune the model for every new task.
- **Versatility**: Works for tasks the model wasn't explicitly trained on, as long as the task can be described in a prompt.

Model Selection:

For zero-shot classification, we'll use the flan-t5-large model, which is well suited for this task due to its size and broad understanding of language. Since this model doesn't require fine-tuning, we can focus on testing its performance directly.

Zero-Shot Intent Classification with Flan-T5

We'll now use the **Flan-T5 large** model to classify intents via zero-shot learning. This approach involves crafting a **prompt** that describes the task and provides the model with the possible labels. The model then uses its language understanding to predict the intent without task-specific training.

Prompt Construction

The prompt is key to zero-shot learning. For our task:

- 1. The prompt begins by instructing the model to classify the intent of the message.
- 2. It lists the available intent categories.
- 3. Finally, it appends the message to classify.

```
for label in label_counts.keys():
    prompt += f"- {label}\n"
prompt += "Message: "

print(prompt)
```

Classify the intent of the following message using these categories:

- get invoice
- payment issue
- create account
- check invoice
- track refund
- check payment methods
- contact human agent
- change shipping address
- review
- complaint
- get refund
- track order
- check cancellation fee
- switch account
- recover password
- place order
- registration problems
- cancel order
- contact customer service
- edit account
- delivery period
- delete account
- check refund policy
- set up shipping address
- change order
- newsletter subscription
- delivery options

Message:

```
In [6]: from transformers import T5Tokenizer, T5ForConditionalGeneration

# Load the tokenizer and model
tokenizer = T5Tokenizer.from_pretrained("google/flan-t5-large")
model = T5ForConditionalGeneration.from_pretrained("google/flan-t5-large", c
```

You are using the default legacy behaviour of the <class 'transformers.model s.t5.tokenization_t5.T5Tokenizer'>. This is expected, and simply means that the `legacy` (previous) behavior will be used so nothing changes for you. If you want to use the new behaviour, set `legacy=False`. This should only be s et if you understand what it means, and thoroughly read the reason why this was added as explained in https://github.com/huggingface/transformers/pull/2 4565

```
In [7]: # Function for zero-shot classification
def zero_shot_intent_classification(model, prompt, message):
    # Combine the prompt and the message
    input_text = prompt + message
    # Tokenize the input text
    input_ids = tokenizer(input_text, return_tensors="pt").input_ids.to(devi
    # Generate a prediction
```

```
output = model.generate(input_ids, max_length=50, num_beams=5, early_stc
# Decode the prediction into text
return tokenizer.decode(output[0], skip_special_tokens=True)

# Test the function
zero_shot_intent_classification(model, prompt, "I need to cancel my order")
```

Out[7]: 'cancel order'

Testing Zero-Shot Intent Classification

You can now test the zero-shot classification capabilities of the flan-t5-large model on a subset of messages from the test set. This will provide a sense of how well the model performs without task-specific training.

```
In [8]: for message in intents['test']['message'][25:35]:
            print(f"Message: {message}")
            print(f"Predicted Intent: {zero shot intent classification(model, prompt
            print()
       Message: delete Gold account
       Predicted Intent: delete account
       Message: I am trying to unsubscribe to the newsletter
       Predicted Intent: newsletter subscription
       Message: what do I need to do to change to the free account?
       Predicted Intent: switch account
       Message: open anotherstandard account
       Predicted Intent: create account
       Message: I'd like to switch to the damn Premium account how to do it
       Predicted Intent: switch account
       Message: editing standard account
       Predicted Intent: edit account
       Message: wanna order several items help me
       Predicted Intent: place order
       Message: problems with standard account terminations
       Predicted Intent: contact customer service
       Message: want help ti earn some of ur product
       Predicted Intent: place order
       Message: I need help notifying of a trouble with online payment
       Predicted Intent: payment issue
```

Predicting Intent At Scale

To evaluate the performance of the flan-t5-large zero-shot model on the entire test dataset, we'll:

- 1. **Generate Predictions**: Use the zero_shot_intent_classification function to predict intents for all test messages.
- 2. **Compare Predictions**: Compare the zero-shot predictions to the true labels in the test set.
- 3. **Examine mis-classified text**: Look at incorrectly classified examples to see if we can understand what went wrong.

```
In [9]: from tqdm import tqdm
       zero shot predictions = [zero shot intent classification(model, prompt, mess
       true labels text = intents['test']['label']

In [10]: from sklearn.metrics import accuracy_score
 print(f'Accuracy: {accuracy_score(true_labels_text, zero_shot_predictions)}

Accuracy: 0.712082262210797

Incredibly, our accuracy using zero-shot learning is around **70%**, even without training on the categories first! Let's take a look at accuracy by category to see if there are any that the model struggles on. The **classification report** will break down the performance of the model by category, allowing us to understand if some categories are less well supported by the model than others. It provides us with the following information:

• **Precision**: This measures the proportion of correctly predicted positive observations to the total predicted positives. High precision indicates that the model makes few false positive errors.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives}$$

- Example: If the task is to classify emails as "spam," a true positive is an email correctly classified as spam, while a false positive is a legitimate email incorrectly classified as spam.
- **Recall**: This measures the proportion of correctly predicted positive observations to all the actual positives. High recall indicates that the model captures most of the true positive cases.

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives}$$

- **Example**: In the same email classification task, a **true positive** is an email correctly classified as spam, while a **false negative** is a spam email incorrectly classified as legitimate.
- **F1 Score**: This is the harmonic mean of precision and recall, balancing the two metrics. A high F1 score indicates a good trade-off between precision and recall.

$$ext{F1 Score} = 2 imes rac{ ext{Precision} imes ext{Recall}}{ ext{Precision} + ext{Recall}}$$

• **Support**: This refers to the number of actual occurrences of each category in the dataset. It helps us understand the distribution of the categories and whether any are underrepresented, which can impact performance metrics.

```
In [11]: from sklearn.metrics import classification_report
    print(classification_report(true_labels_text, zero_shot_predictions, zero_di

Flagging Abuse

One of the challenges in customer service is identifying and handling abusive messages. Even in this dataset there are examples where customers have used inappropriate language in their requests.

```
In [13]: # Display abusive examples
pd.DataFrame([(message, label) for message, label in zip(intents['test']['megantary)
```

	Wiessage	Label
0	i have got to request goddamn erimbursements o	get refund
1	I'd like to switch to the damn Premium account	switch account
2	i cannot sign up where to notify of goddamn si	registration problems
3	I don't know how to demand a goddamn restituti	get refund
4	can you help me informing of a goddamn signup	registration problems
5	I need a damn Platinum account, could I open it?	create account
6	could you help me to close the damn free account?	delete account
7	I want to delete a goddamn item from order 732	change order
8	I call to check what damn shipping methods are	delivery options
9	where can I see what damn shipment options you	delivery options

Message

Label

Out[13]:

Out[14]: 'Inappropriate'

Let's say that we want to introduce a new task to classify messages as abusive or not. We can use the same zero-shot approach to classify messages as abusive or not abusive. The prompt will be similar to the previous one, but with the new task and labels.

```
In [14]: # Define the prompt for abusive language classification
         abuse prompt = "Classify the following as inappropriate if it contains cursi
         # Load the tokenizer and model
         abuse tokenizer = T5Tokenizer.from pretrained("google/flan-t5-large")
         abuse model = T5ForConditionalGeneration.from pretrained("google/flan-t5-lar
         # Function for zero-shot classification of abusive language
         def zero shot abuse classification(model, prompt, message):
             # Combine the prompt and the message
             input text = prompt + message
             # Tokenize the input text
             input ids = abuse tokenizer(input text, return tensors="pt").input ids.t
             # Generate a prediction
             output = model.generate(input ids, max length=50, num beams=5, early std
             # Decode the prediction into text
             return abuse_tokenizer.decode(output[0], skip_special_tokens=True)
         # Test the function
         zero shot abuse classification(abuse model, abuse prompt, "I'm so damn frust
```

Now we can use the model to flag messages as inappropriate or not inappropriate:

```
In [15]: # Predict for samples that contain the word "damn"
for message in intents['test']['message']:
```

```
if 'damn' in message.lower():
    print(f"Message: {message}")
    print(f"Predicted Intent: {zero_shot_abuse_classification(abuse_mode
    print()
```

Message: i have got to request goddamn erimbursements of my money Predicted Intent: Inappropriate

Message: I'd like to switch to the damn Premium account how to do it Predicted Intent: Inappropriate

Message: i cannot sign up where to notify of goddamn signup problems Predicted Intent: Inappropriate

Message: I don't know how to demand a goddamn restitution of my money Predicted Intent: Inappropriate

Message: can you help me informing of a goddamn signup issue? Predicted Intent: Inappropriate

Message: I need a damn Platinum account, could I open it? Predicted Intent: Inappropriate

Message: could you help me to close the damn free account? Predicted Intent: Inappropriate

Message: I want to delete a goddamn item from order 732201349959 Predicted Intent: Inappropriate

Message: I call to check what damn shipping methods are available Predicted Intent: Inappropriate

Message: where can I see what damn shipment options you offer? Predicted Intent: Inappropriate

Translation

Finally, let's explore how we can use transformers for translation tasks. We'll start by translating English messages to French using the translation_en_to_fr pipeline. Then we'll look at translating to Japanese using a different model.

```
In [16]: from transformers import pipeline
    en_fr_translator = pipeline("translation_en_to_fr", device='cuda')
# Translate a sample message
    en_message = "I need help with my order."
    en_fr_translator(en_message)
```

No model was supplied, defaulted to google-t5/t5-base and revision a9723ea (https://huggingface.co/google-t5/t5-base).
Using a pipeline without specifying a model name and revision in production is not recommended.

```
Out[16]: [{'translation_text': "J'ai besoin d'aide pour faire ma commande."}]
In [17]: # Translate first 50 messages in the test set
    en_messages = intents['test']['message'][:50]
    fr_messages = en_fr_translator(en_messages)

# Display the translations
for en_message, fr_message in zip(en_messages, fr_messages):
    print(f"EN: {en_message}\nFR: {fr_message['translation_text']}\n")
```
